

Health risk due to nanoparticles - epidemiological knowledge

H.-Erich Wichmann

**GSF – Institute of Epidemiology
LMU – University of Munich, Germany**

***ETH-Conference on Combustion Generated
Particles, Zürich 16 – 18 August 2004***

Content

- **Ambient concentrations**
- **Respiratory effects**
- **Cardiovascular effects**
- **Summary**

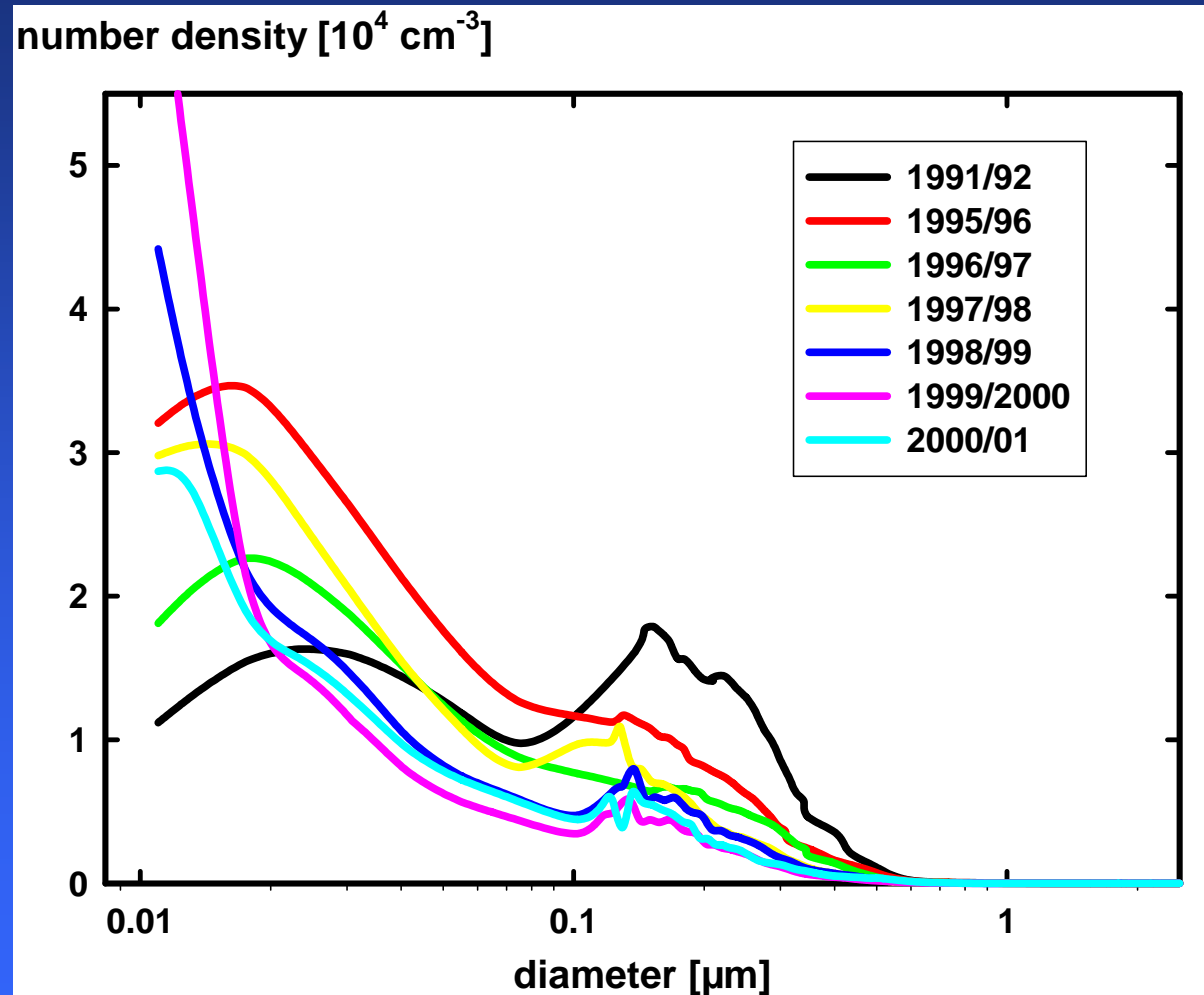

Abbreviations:

PM ₁₀	fine and coarse particles	(mass)	< 10 μm
FP	fine particles	(mass)	< 2.5 μm
UP	ultrafine particles	(number)	< 0.1 μm

UP = nanoparticles

Particle distribution in Erfurt

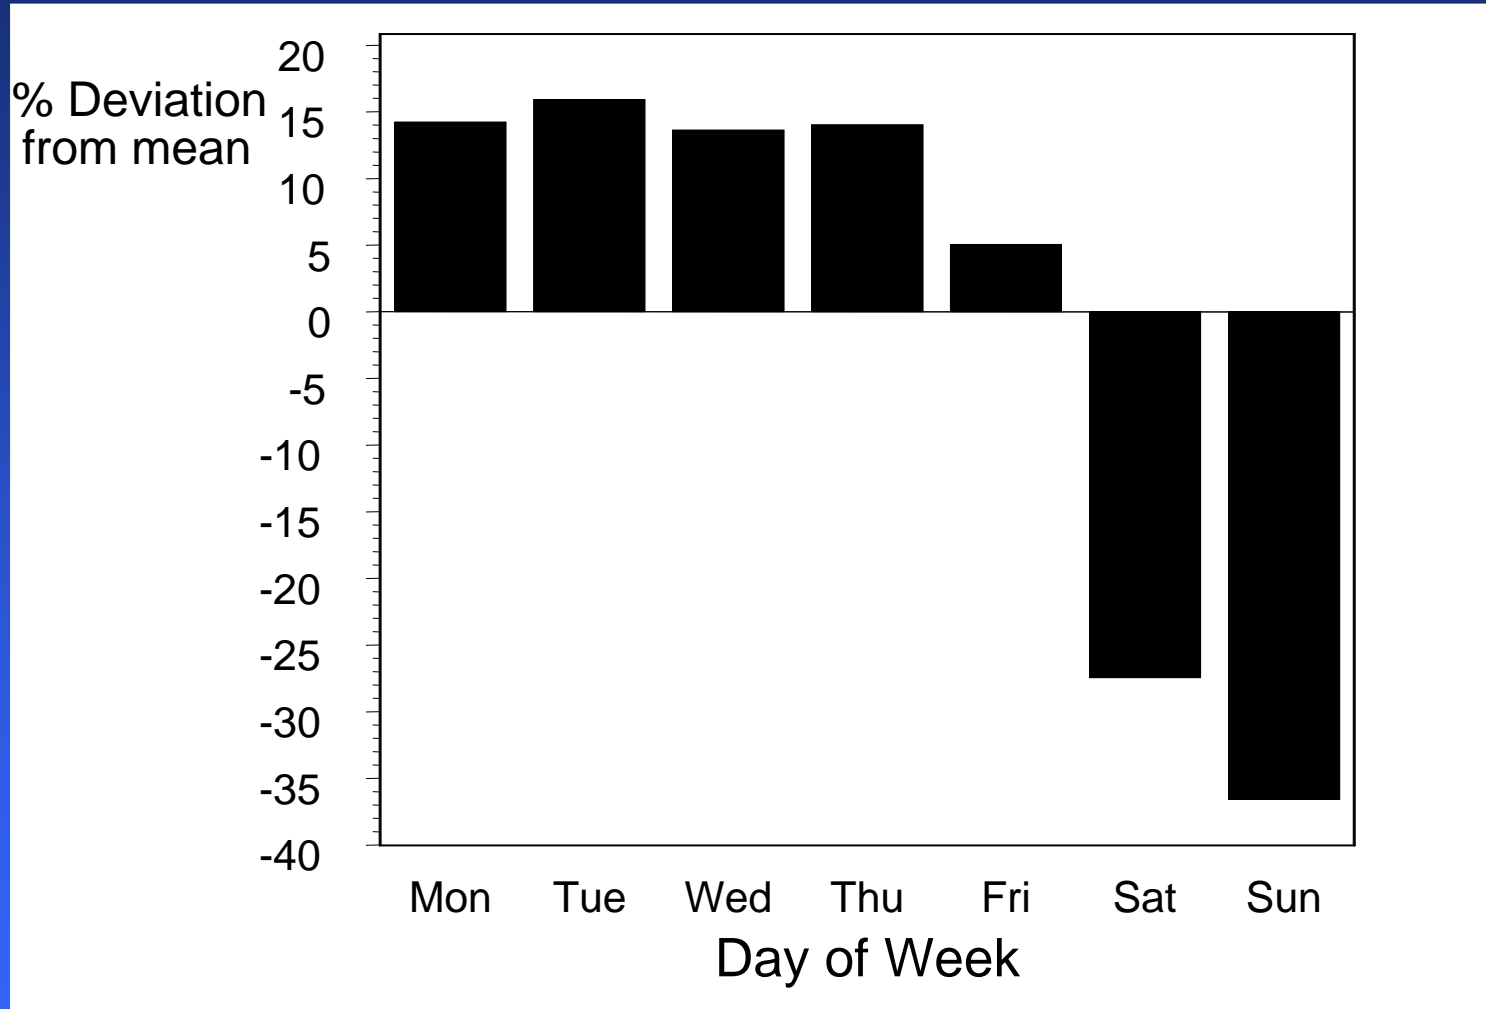

Relative particle number, BC, CO concentrations versus distance from the 710 freeway

Zhu et al (2002)

Day of week pattern of UP

Ultrafine Particles at conventional workplaces

- Fumes from hot processes (e.g. smelting and refining metals; welding)
- Fumes from combustion processes (e.g. diesel motor emissions, carbon black manufacture)
- Bioaerosols (e.g. agriculture, biotechnology)

Who is susceptible and why?

Inhalation of ambient particles

Local effects
Inflammation

Systemic effects
Acute phase proteins
Cytokines

Asthma Attacks
Acute Bronchitis

Ischemia
Arrhythmia

Particulate matter was associated with mortality

Role of ultrafine particles

- Ultrafine particles are deposited in the alveolar region with high efficiency.
- The large surface of ultrafine particles can increase toxicity.
- Decreased phagocytosis allows enhanced interaction between ultrafine particles and the epithelium
- Ultrafine particles are dislocated from the alveolar space and might therefore elicit systemic effects.

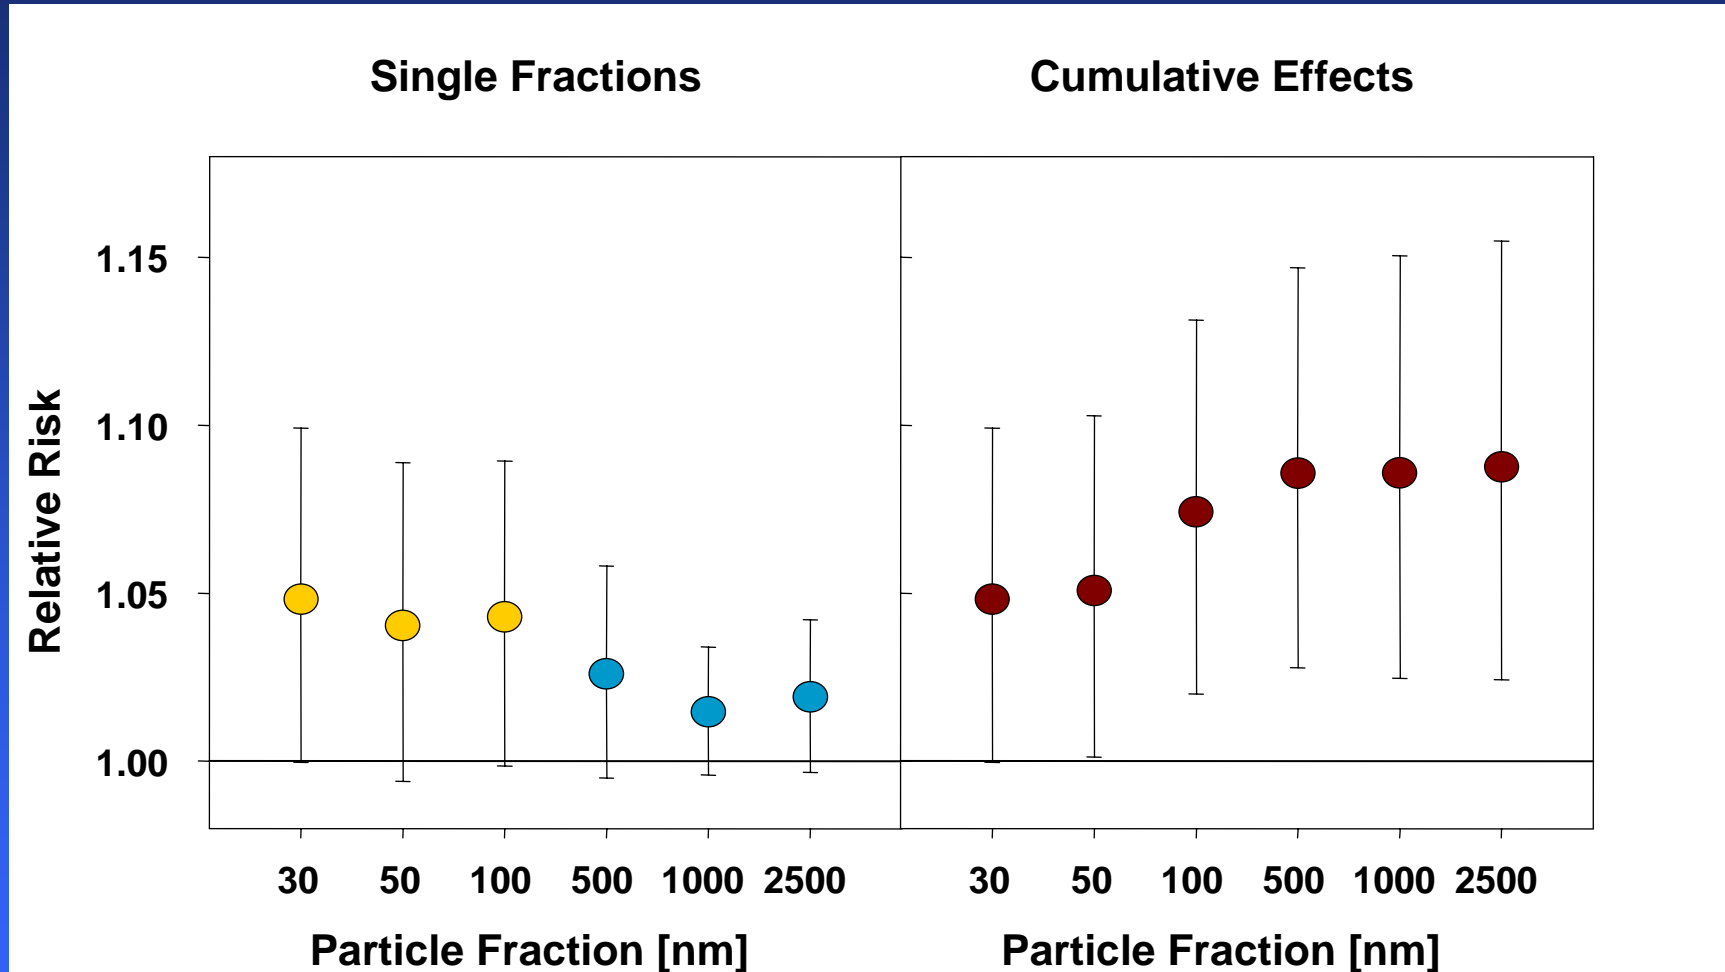

Mortality Study on ultrafine particles

- Daily mortality counts were collected in Erfurt between summer 1995 and the end of 1998.
- Particle size distributions were measured with an aerosol spectrometer between 10 nm and 2.5 μm .
- Ultrafine particles were only moderately correlated with $\text{PM}_{2.5}$.

Wichmann et al. *HEI Report 2000*

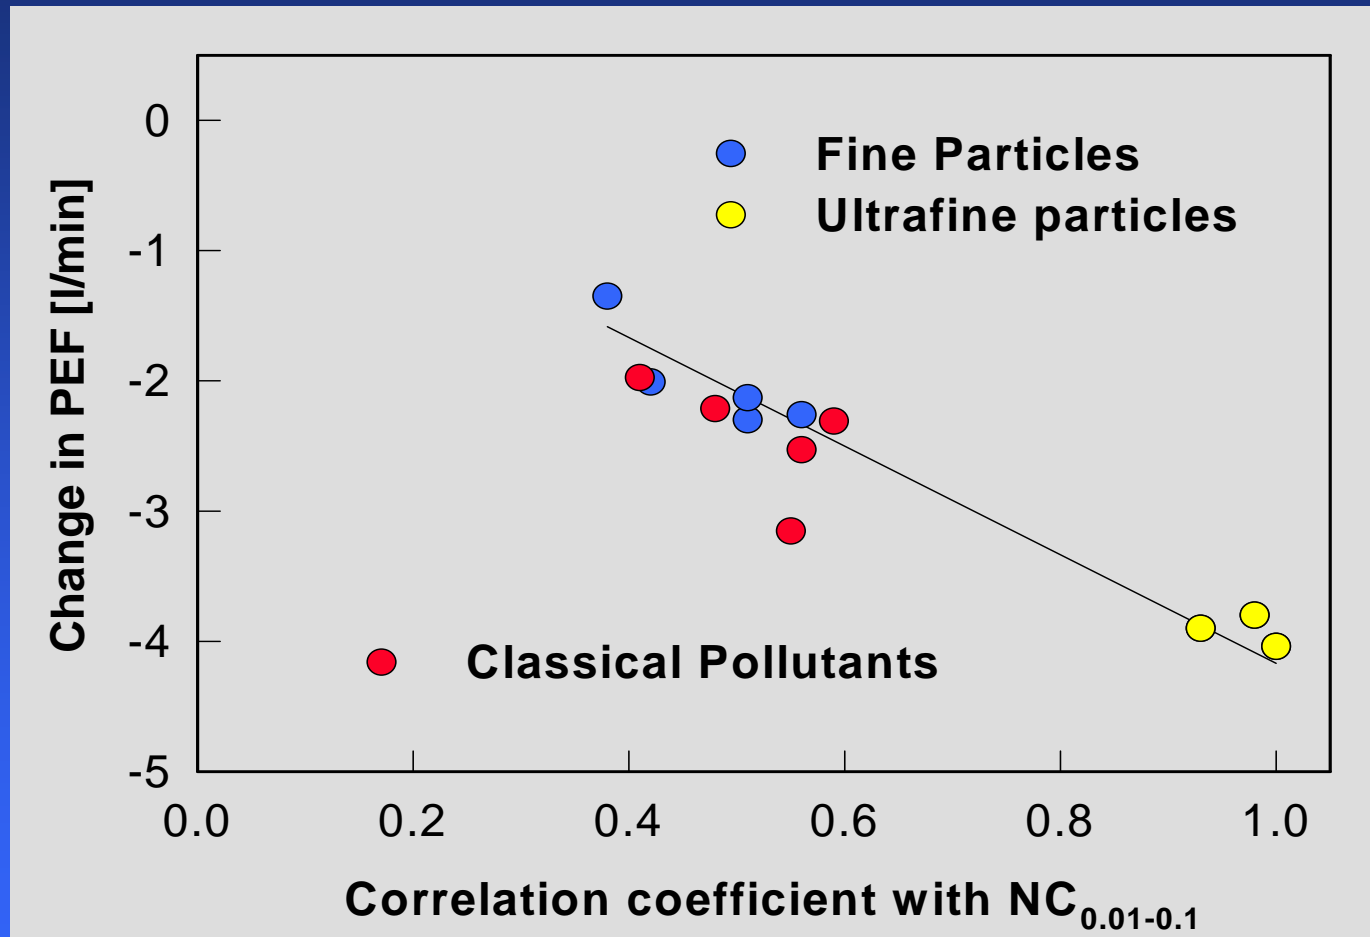

Particle and Daily Mortality, 1995 to 1998, Erfurt

Regression results by cause of death

Lung function reduction in asthmatic adults

Medication use increased in adult asthmatics (Erfurt)

52 subjects followed for 5 months during winter 96/97

Potential mechanism leading to cardiovascular effects

- Increased sympathetic activation and /or withdrawal of parasympathetic tone
- Imbalance of sympathetic and parasympatetic control
- Decreased heart rate variability
- Increased risk for cardiac events (alteration of myocardial substrate, increased myocardial vulnerability)

Particles and Myocardial Infarction in Augsburg

Traffic and Onset of Myocardial Infarction in Augsburg

- 691 MI survivors of the KORA MI Registry Augsburg
- Activities were recorded 4 days before the event
- Using a car, public transport or a bicycle might be a risk factor for MI

Rochester Particle Center Study in Erfurt, Germany

- Panel Study in 56 patients with coronary artery disease (winter 2000/01)
- Panel Study in 37 patients with chronic obstructive pulmonary disease (winter 2001/02)
- Blood biomarkers and EKG recordings at 12 clinic visits
- Central monitoring of ultrafine and accumulation mode particles, PM_{2.5}

Particle effects on normalized HF in Erfurt

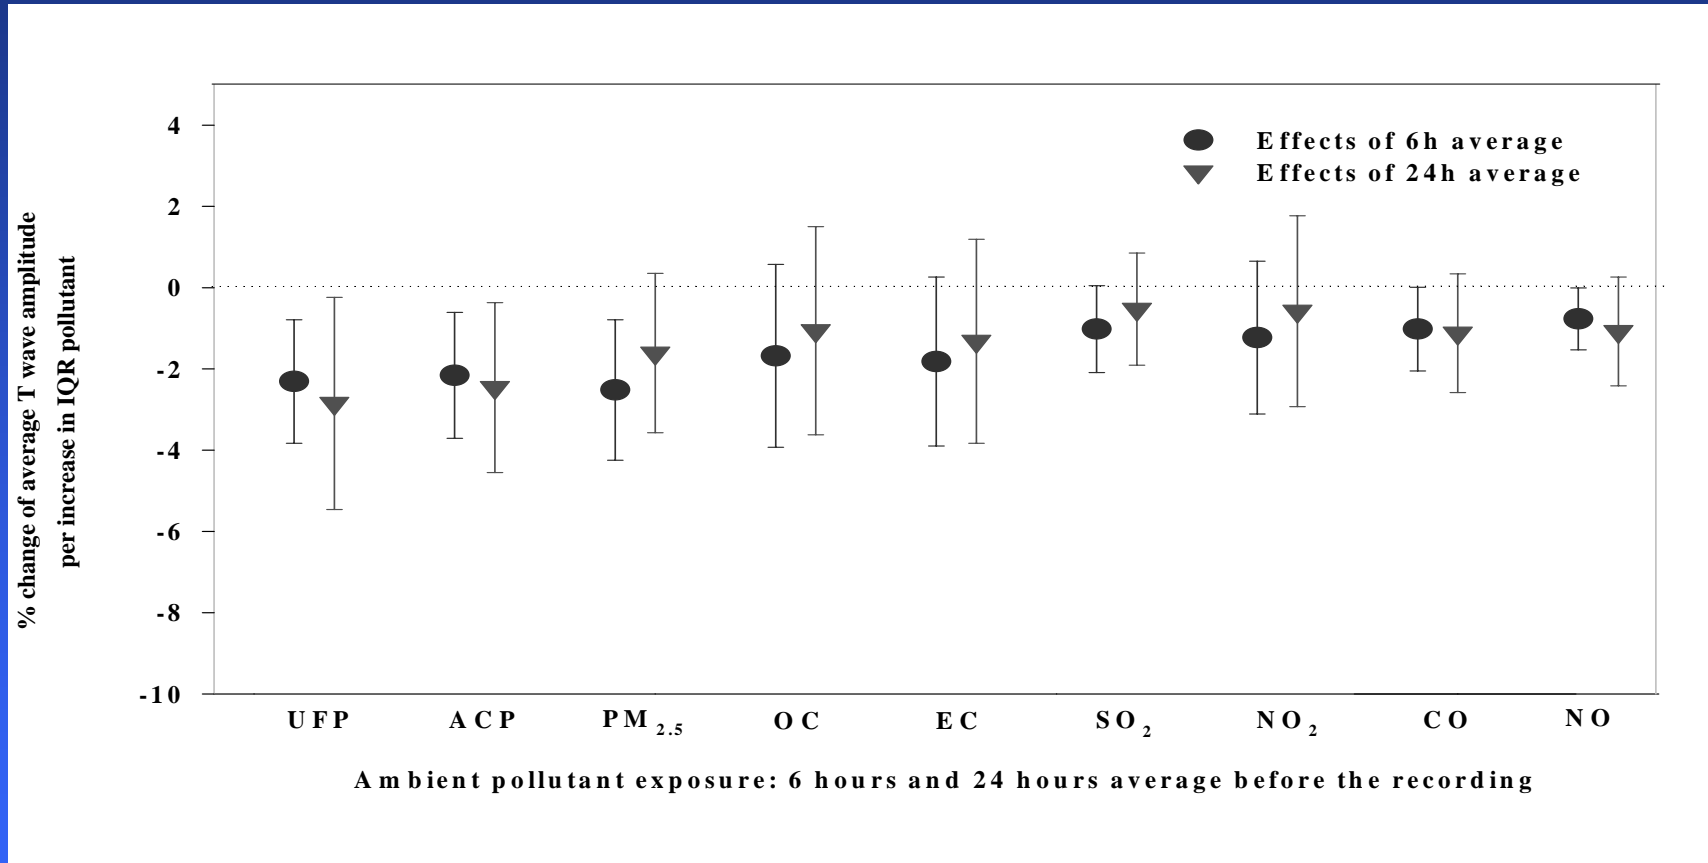

spontaneous breathing, 5 min recordings

Ultrafine Particle number, PM_{2.5} and Temperature (CAD panel, Erfurt, winter 2000/2001)

Particle effects on T wave amplitude in Erfurt spontaneous breathing, 5 min recordings

Particle effects on T wave complexity in Erfurt spontaneous breathing, 5 min recordings

Summary

- Main ambient source of UP is automobile traffic
- Health effects of UP on respiratory and cardiovascular endpoints shown, but open questions
- Epidemiology on technically produced nanoparticles missing (work place and environment)
- Epidemiology on UP from combustion may serve as model for nanoparticles
